LLM-para

— . Moe

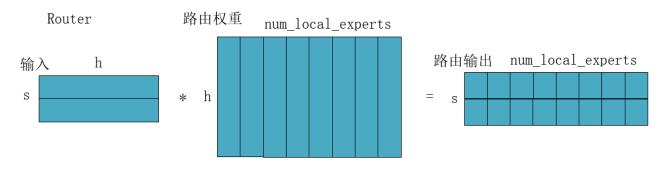

1. 启用MoE

```
1  use_moe = False
2  # 如果传入 moe 参数 则启用moe计算
3  if num_experts_per_tok is not None:
4  use_moe = True
```

2. Prefill MoE 参数计算

分解	Input1	Input2	Output	运算量
MoE_Router	(b,s,h)	(h,num_local_experts)	(b,s,num_local_experts)	2bsh*num_local_experts
MoE_FFN1	(b, s*num_experts_per_tok , h)	(num_local_experts,h, intermediate_size*2)	(b,s*num_experts_per_tok ,intermediate_size * 2)	2bs* num_experts_per_tok * h * intermediate_size * 2 + bs * num_experts_per_tok * intermediate_size
MoE_FFN2	(b,s*num_experts_per_tok, intermediate_size)	(num_local_experts, intermediate_size, h)	(b, s*num_experts_per_tok , h)	2bs * num_experts_per_tok * intermediate_size * h

路由参数计算

```
moe_router_flops = b * seq * h * num_local_experts * 2
param_count = h * num_local_experts
add_row(phase, "Router", "(b,s,h)", f"(h,{num_local_experts})", f"(b,s,{num_local_experts})",
moe_router_flops, param_count,
(b,seq,h), (h,num_local_experts), (b,seq,num_local_experts), a_bit, w_ffn)
```

FFN-1计算

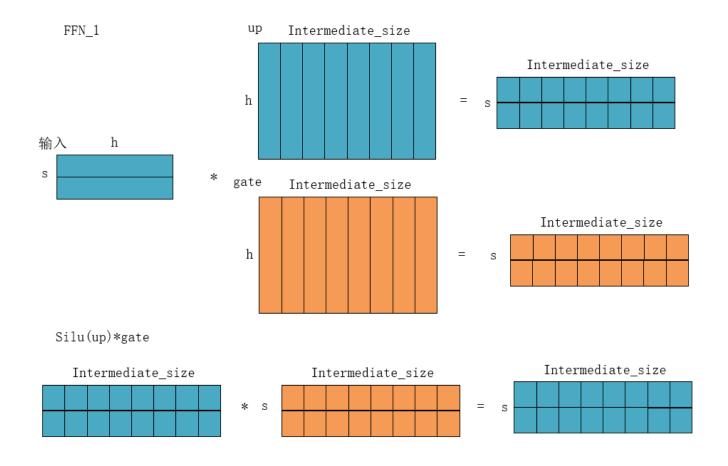

假设prefill输入seq足够大,大到能够使用到所有expert。

输入形状为**(b,s*num_experts_per_tok,h)**:对于每个token,需要送入到num_experts_per_tok个MLP进行计算,则相当于将每个token复制了num_experts_per_tok次,即有seq*num_experts_per_tok个token。

输入权重形状为(num_local_experts,h,intermediate_size*2):使用到所有expert,且加载up和gate的权重。

所需参数量: num_experts_per_tok个 up+gate 权重矩阵

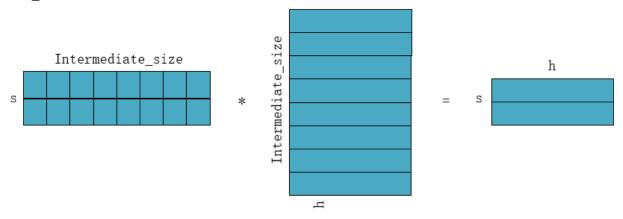

```
1 # FFN-1(up + gate)(with Moe)
   FFN_1_moe = b * seq * num_experts_per_tok * h * intermediate_size * 2 * 2 # * 两个矩阵乘
   法 * 每个token算num_experts_per_tok次
3
  # 额外的逐元素乘法
  FFN_1_moe += b * seq * num_experts_per_tok * intermediate_size # (W₁x) ⊙ SiLU(W_gate*x)
4
5
   param_count = h * intermediate_size * 2 * num_local_experts # 两个权重矩阵 * 假设 prefill
6
   用到了所有expert
   add_row(phase, "FFN-1(with Moe)", f"(b,{s}*num_experts_per_tok,h)", f"
7
   (num_local_experts,h,{intermediate_size}*2)", f"(b,{s}*num_experts_per_tok,
   {intermediate_size}*2)",
8
           FFN_1_moe, param_count,
9
           (b, seq * num_experts_per_tok, h), (h, intermediate_size * 2 *
   num_local_experts), (b, seq * num_experts_per_tok, intermediate_size*2 ), a_bit, w_ffn)
```

FFN-2 计算

```
# FFN-2(with Moe)
FFN_2_moe = b * seq * intermediate_size * h * 2 * num_experts_per_tok
param_count = intermediate_size * h * num_local_experts
add_row(phase, "FFN-2(with Moe)", f"(b, {s}*num_experts_per_tok, {intermediate_size})",
f"(num_local_experts, {intermediate_size}, h)", f"(b,
{s}*num_experts_per_tok,h)",FFN_2_moe, param_count,
(b, seq * num_experts_per_tok, intermediate_size), (intermediate_size, h,
num_local_experts), (b, seq * num_experts_per_tok, h), a_bit, w_ffn)
```

FFN 2

3. Decode MoE参数计算

prefill 阶段的计算每次需要加载num_local_experts个MLP的参数。

decode 阶段的计算每次只需要加载num_experts_per_tok个MLP的参数。

4. 计算结果对比 (mixtral-8x7B)

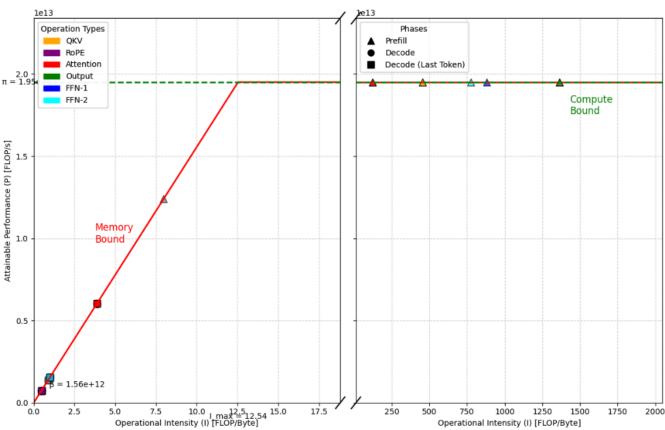

增加Moe功能后,prefill阶段的FFN推理计算密度约为800;同一模型配置,去掉Moe功能,prefill阶段的FFN推理计算密度增加至约为2000。而decode阶段,对于FFN的推理其计算密度都为1。可得,增加Moe功能后,prefill阶段的FFN推理朝着更带宽受限的方向转变。

With Moe仿真结果

```
1 | num_experts_per_tok = 2
2 | num_local_experts = 8
```
